

SQL Programming

Set Functions

In this module we discuss one of the most powerful features of the SQL language: Group Functions.

Group functions are functions that apply to groups of rows.

Now the 'more better' way to refer to these functions is to think of them as set functions, as this is the terminology that is used in the standard.

Set functions is a more precise term and harkens back to the set theoretical underpinnings of relational db theory. But, for now, let's focus on developing your intuitions, and use the term group functions for just a little while longer.

These group functions operate on a group of rows and return a single value (or single row) of results.

This ability to distill and aggregate data has prompted many users to refer to these functions as aggregate functions.

The aggregate functions defined by the standard give the SQL programmer a handy way to gather and display statistics about the data.

<u>Statistic</u>	<u>Function</u>
tally	COUNT()
total	SUM()
high value	MAX()
low value	MIN()
average	AVG()

This function is used to answer the question, 'How many?'

The COUNT function accepts one of two parameters, either the name of a column, or the special character '*':

COUNT(*column-name*)

COUNT(*)

Count with the column-name parameter, counts the number of values in the specified column, and in this tally, NULL values are omitted.

Count with the asterisk parameter returns the count, or tally, of the number of rows.

Module 12: Set Functions

Page C-2 Count(*column-name*)

The screenshot shows the iSQL*Plus web interface in a Microsoft Internet Explorer window. The browser title is "iSQL*Plus Release 9.0.1 - Microsoft Internet Explorer provided by Cox High S...". The interface includes a menu bar (File, Edit, View, Favorites, Tools, Help) and a toolbar with icons for Password, Log Out, and Help. The main content area has a "Script Location:" field with a "Browse..." button and a "Load Script" button. Below this is a text area for "Enter statements:" containing the SQL query:

```
SELECT COUNT(id)
FROM talent;
```

 At the bottom of the interface are buttons for "Execute", "Output:" (with a dropdown menu set to "Work Screen"), "Clear Screen", and "Save Script". The "Output:" section displays the result of the query in a table with one row:

COUNT(ID)
25

 The status bar at the bottom shows "Done" and "Internet".

Consider the question:

How many clients do we have?

Since the question is asking 'How many', we know that we want to use the count function.

The next question for the programmer to answer then is, which column is it that we should be counting? In this problem, I ask myself, is there any column that I'm sure has a valid value for each and every one of our clients?

Design and code:

```
SELECT COUNT(id)
FROM talent;
```

Module 12: Set Functions

Page C-3 Count(*)

The screenshot shows the iSQL*Plus web interface in a Microsoft Internet Explorer browser window. The title bar reads "iSQL*Plus Release 9.0.1 - Microsoft Internet Explorer provided by Cox High S...". The browser's menu bar includes File, Edit, View, Favorites, Tools, and Help. The iSQL*Plus header features the Oracle logo, the text "iSQL*Plus", and links for Password, Log Out, and Help. Below the header, there is a "Script Location:" field with a "Browse..." button and a "Load Script" button. The "Enter statements:" section contains a text area with the SQL query:

```
SELECT COUNT(*)  
FROM talent;
```

 Below the text area are buttons for "Execute", "Output:" (with a dropdown menu set to "Work Screen"), "Clear Screen", and "Save Script". The "Output:" section displays a table with one row:

COUNT(*)
25

. The browser's status bar at the bottom shows "Done" and "Internet".

Instead of counting known values in columns, I could have simply counted rows:

Design and code:

```
SELECT COUNT(*)  
FROM talent;
```

Let's refine our terminology.

Count(*) counts rows, right?

Count(*column-name*) counts rows in that column with known values (ie. excludes NULLs), right?

Module 12: Set Functions

Page C-4 Count and DISTINCT

iSQL*Plus Release 9.0.1 - Microsoft Internet Explorer provided by Cox High S...

File Edit View Favorites Tools Help

ORACLE iSQL*Plus

[Password](#) [Log Out](#) [Help](#)

Script Location:

Enter statements:

```
SELECT COUNT(DISTINCT home_country)
FROM talent;
```

COUNT(DISTINCTHOME_COUNTRY)

5

Done Internet

Consider this problem.

From how many different countries do we draw our clients?

Design and code:

We've got that magic phrase 'How many' so we know this problem will use the COUNT function.

That word 'different' suggests to me that we need to use the DISTINCT phrase.

Let's try:

```
SELECT COUNT(DISTINCT home_country)
FROM talent;
```

The COUNT function is the only function that can account for NULLs (no pun intended).

Hence, it is the only function that may take the asterisk as a parameter

Every other function disregards NULL values and does not factor them in to the operation.

This function is used to find the smallest value in a column.

Character columns return the 'smallest' value based on the collating sequence of the character set being used. In ASCII, the letter 'a' occurs earlier in the collating sequence than the letter 'g', hence 'a' is less than 'g'.

To collate a list means to arrange the items in that list in some order.

A collating sequence is the rule for ordering a list of items.

A good example of collating is alphabetizing (ie. sorting). The collating sequence for the English alphabet is the list of letters arranged in this order:

abcdefghijklmnopqrstuvwxyz.

In computing we use the term collating rather than alphabetizing, because alphabetizing is restricted to only letters in the alphabet.

In computing we're concerned with sorting more than just the letters of the alphabet, we need to be able to arrange all of the characters in the character set according to some rule.

That rule is the collating sequence, and each character set has its own collating sequence.

And, on some platforms, the programmer can customize the collating sequence for her needs.

Module 12: Set Functions

Page D-3 MIN w/ Date Values

When used with a date value, MIN returns the earliest date in that column.

When used with a numeric value, MIN returns the smallest value in the column.

The screenshot shows the iSQL*Plus web interface in a Microsoft Internet Explorer browser window. The browser title is "iSQL*Plus Release 9.0.1 - Microsoft Internet Explorer provided by Cox High...". The interface includes a menu bar (File, Edit, View, Favorites, Tools, Help) and a toolbar with icons for Password, Log Out, and Help. The main content area has a "Script Location:" field with a "Browse..." button and a "Load Script" button. Below this is a text area for "Enter statements:" containing three SQL queries:

```
SELECT MIN(home_country)
FROM   talent;

SELECT MIN(birthdate)
FROM   talent;

SELECT MIN(id)
FROM   talent;
```

Below the queries are three buttons: "Execute", "Output:" (with a dropdown menu set to "Work Screen"), "Clear Screen", and "Save Script". The results are displayed in three separate boxes:

- MIN(HOME_COUNTRY)**: Austria
- MIN(BIRTH)**: 03-APR-24
- MIN(ID)**: 507216

The browser status bar at the bottom shows "Done" and "Internet".

Module 12: Set Functions

Page D-3 MAX

MAX is used to find the largest value in a column.

When used with character values, MAX returns the value from the column that occurs latest in the collating sequence.

When used with a date value, MAX returns the latest date in that column.

When used with a numeric value, MAX returns the largest value in the column.

The screenshot shows the iSQL*Plus web interface in a Microsoft Internet Explorer browser window. The browser title is "iSQL*Plus Release 9.0.1 - Microsoft Internet Explorer provided by Cox High...". The interface includes a menu bar (File, Edit, View, Favorites, Tools, Help) and a toolbar with icons for Password, Log Out, and Help. The main content area has a "Script Location:" field with a "Browse..." button and a "Load Script" button. Below this is a text area for "Enter statements:" containing three SQL queries:
`SELECT MAX(home_country)`
`FROM talent;`
`SELECT MAX(birthdate)`
`FROM talent;`
`SELECT MAX(id)`
`FROM talent;`
At the bottom of the script area are buttons for "Execute", "Output:" (with a dropdown menu set to "Work Screen"), "Clear Screen", and "Save Script". Below the script area, the results of the queries are displayed in three separate boxes:
1. The first box is titled "MAX(HOME_COUNTRY)" and shows the result "USA".
2. The second box is titled "MAX(BIRTH)" and shows the result "13-JAN-77".
3. The third box is titled "MAX(ID)" and shows the result "2100716365".
The browser's status bar at the bottom shows "Done" and "Internet".

MIN and MAX are referred to as extrema functions because they return the 'extreme' values, or 'endpoints' in the column.

Module 12: Set Functions

Page E-1 SUM

The screenshot shows the iSQL*Plus web interface in a Microsoft Internet Explorer browser window. The title bar reads "iSQL*Plus Release 9.0.1 - Microsoft Internet Explorer provided by Cox High...". The browser's menu bar includes File, Edit, View, Favorites, Tools, and Help. The iSQL*Plus header features the Oracle logo, the text "iSQL*Plus", and links for Password, Log Out, and Help. Below the header, there is a "Script Location:" field with a "Browse..." button and a "Load Script" button. The "Enter statements:" section contains a text area with the following SQL query:

```
SELECT SUM(perc)
FROM talent;
```

Below the text area are buttons for "Execute", "Output:" (with a dropdown menu set to "Work Screen"), "Clear Screen", and "Save Script". The "Output:" section displays a table with one column header "SUM(PERC)" and one row of data with the value "162".

SUM(PERC)
162

The SUM function is used to total, or add up, the values in a column.

SUM can only be used with numeric data. You cannot SUM character values nor date values.

But just because you *can* do something, doesn't mean that you *should* do something.

And as smart as SQL is, it won't warn you when you do something stooopid.

The SQL program in this example is syntactically correct, and as far as SQL can tell, is semantically correct. But it is utter nonsense. What meaning (other than a description of the activity) does it have?

Module 12: Set Functions

Page E-2 AVG

The AVG function is used to calculate the average (arithmetic mean) of the values in a column.

And just as we saw with the SUM function, the AVG function can only operate on numeric domains.

The screenshot shows the iSQL*Plus web interface in a Microsoft Internet Explorer browser window. The title bar reads "iSQL*Plus Release 9.0.1 - Microsoft Internet Explorer provided by Cox High...". The browser's menu bar includes File, Edit, View, Favorites, Tools, and Help. The iSQL*Plus header features the ORACLE logo, the text "iSQL*Plus", and three circular icons (a person, a key, and a question mark) with links for Password, Log Out, and Help below them. A "Script Location:" field with a "Browse..." button and a "Load Script" button is present. Below this is a text area labeled "Enter statements:" containing the SQL query:

```
SELECT AVG(perc)
FROM talent;
```

 At the bottom of the interface are buttons for "Execute", "Output:" (with a dropdown menu set to "Work Screen"), "Clear Screen", and "Save Script". The "Output:" section displays a table with one row:

AVG(PERC)
6.48

 The browser's status bar at the bottom shows "Done" and "Internet".

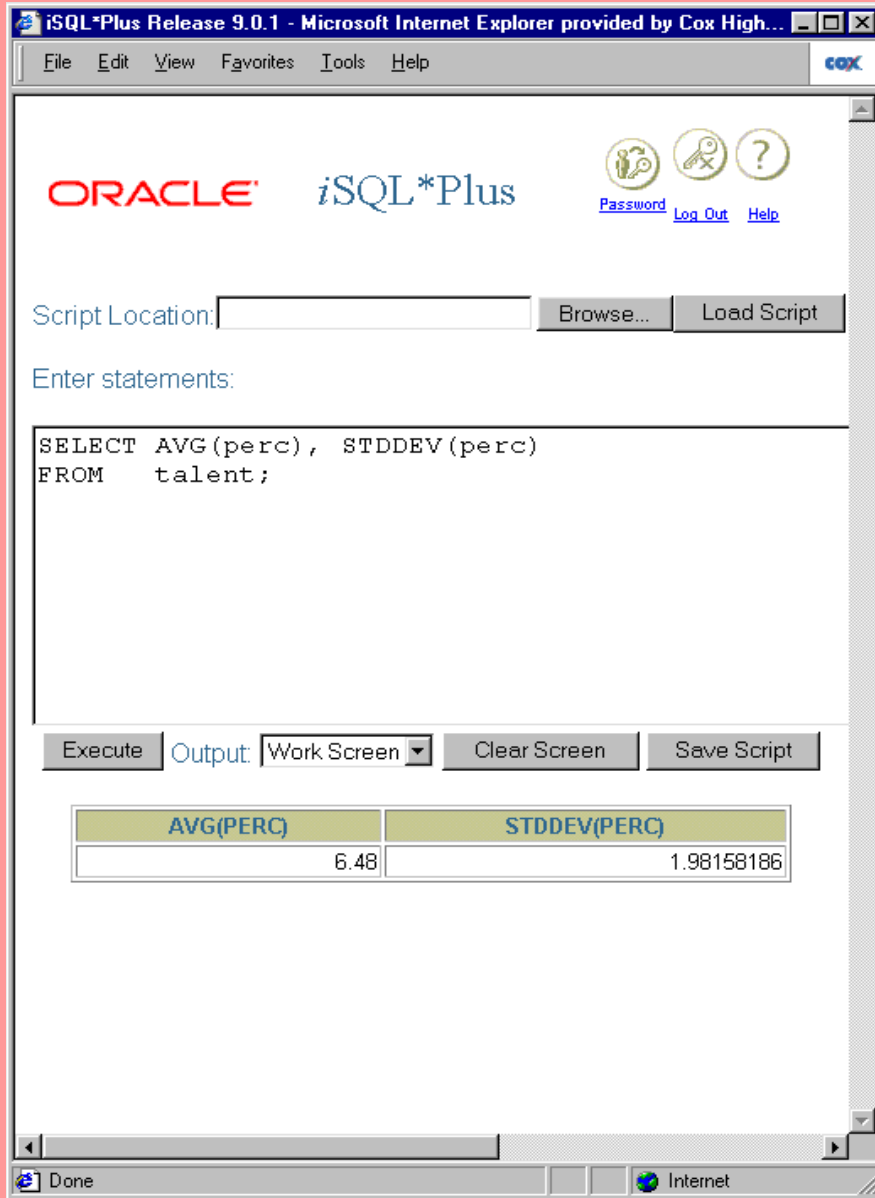

I think of set functions as tools that I can use to gather and display statistics about the data in my database.

Both Oracle and MySQL provide some additional statistical functions.

Function	Oracle	MySQL
Standard Deviation	STDDEV	STD, STDDEV, STDDEV_POP
		STDDEV_SAMP
Variance	VARIANCE	VARIANCE VAR_POP
		VAR_SAMP

Module 12: Set Functions

Page H-2 STDDEV

The screenshot shows the iSQL*Plus web interface in a Microsoft Internet Explorer browser window. The browser title is "iSQL*Plus Release 9.0.1 - Microsoft Internet Explorer provided by Cox High...". The interface includes a menu bar (File, Edit, View, Favorites, Tools, Help) and a toolbar with icons for Password, Log Out, and Help. The main content area has a "Script Location:" field with a "Browse..." button and a "Load Script" button. Below this is a text area for "Enter statements:" containing the SQL query:

```
SELECT AVG(perc), STDDEV(perc)
FROM talent;
```

 At the bottom of the interface are buttons for "Execute", "Output:" (with a dropdown menu set to "Work Screen"), "Clear Screen", and "Save Script". The results are displayed in a table with two columns: "AVG(PERC)" and "STDDEV(PERC)".

AVG(PERC)	STDDEV(PERC)
6.48	1.98158186

The standard deviation is a measure of variation from the mean. In other words, it helps you visualize how all of the data is clustered around the mean.

In my opinion, knowing the average value for any data set is almost meaningless unless it is accompanied by some information about the variation of the data.

I'm not going to delve any further into 'statistical realms'. If you understand and appreciate the value of metrics such as the standard deviation and the variance, just know that Oracle provides set functions that will easily calculate those values for you.

If you don't appreciate these metrics, then get thee to a stats class ; -)

Module 12: Set Functions

Page H-3 VARIANCE

VARIANCE is another measure of the variation of the data about the mean.

The screenshot shows the iSQL*Plus web interface in a Microsoft Internet Explorer browser window. The browser title is "iSQL*Plus Release 9.0.1 - Microsoft Internet Explorer provided by Cox High...". The interface includes a menu bar (File, Edit, View, Favorites, Tools, Help) and a toolbar with icons for Password, Log Out, and Help. The main content area has a "Script Location:" field with a "Browse..." button and a "Load Script" button. Below this is a text area for "Enter statements:" containing the SQL query:

```
SELECT AVG(perc), STDDEV(perc), VARIANCE(perc)
FROM talent;
```

 At the bottom of the interface are buttons for "Execute", "Output:" (with a dropdown menu set to "Work Screen"), "Clear Screen", and "Save Script". The results are displayed in a table with three columns: AVG(PERC), STDDEV(PERC), and VARIANCE(PERC). The values are 6.48, 1.98158186, and 3.92666667 respectively. The browser status bar at the bottom shows "Done" and "Internet".

AVG(PERC)	STDDEV(PERC)	VARIANCE(PERC)
6.48	1.98158186	3.92666667

The statistics functions in Oracle are population statistics. MySQL gives you the option of calculating these statistics as either *population* or *sample* statistics.

The distinction between these two functions is based on whether we are treating the data as the entirety of the population of data (all of the data), or 'just' a sample of the data.

For the population calculation, the denominator is the number of rows.

For the sample calculation, the denominator is the number of rows, less 1.

The screenshot shows the MySQL Query Browser interface. The query entered is:

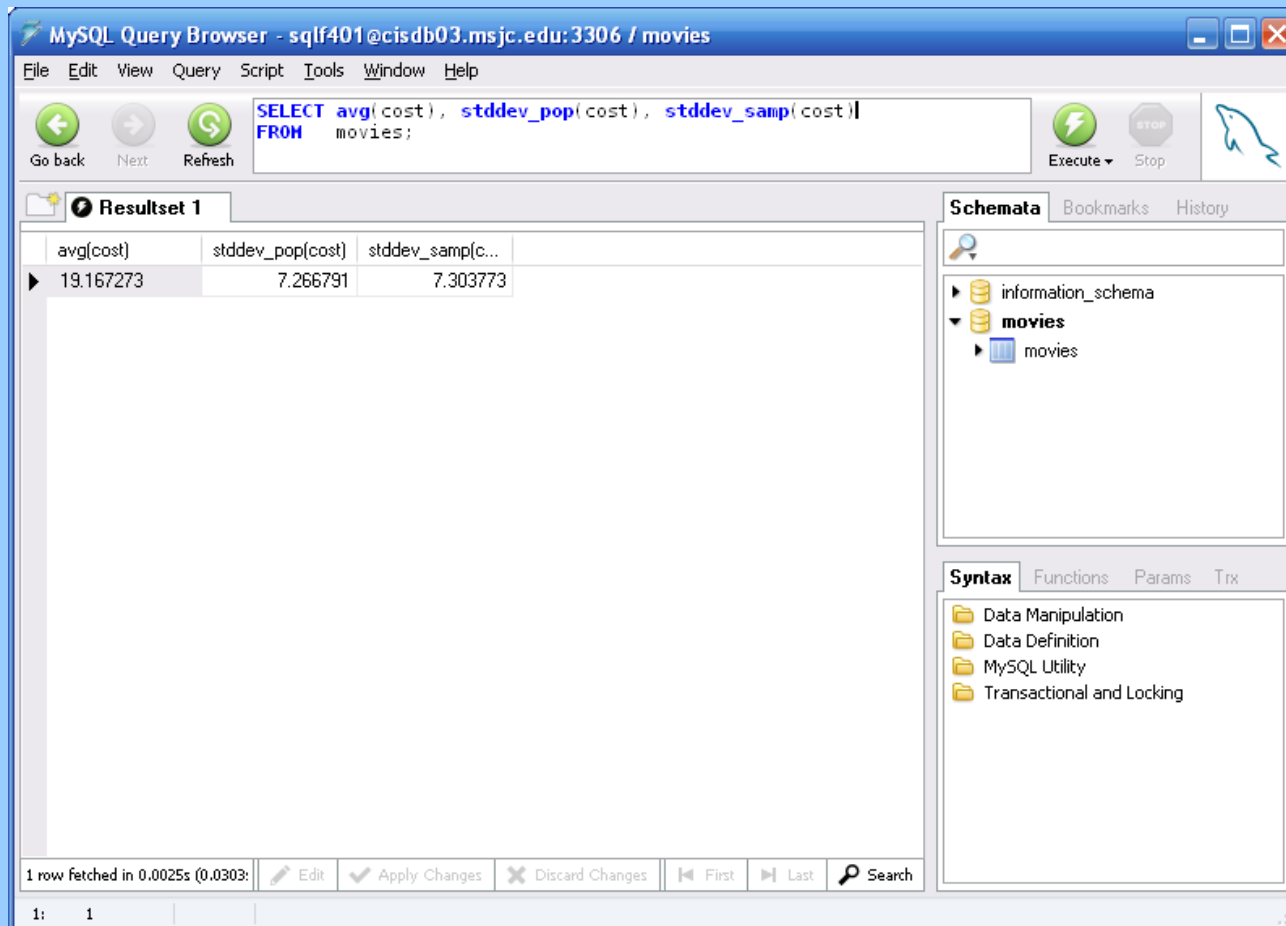

```
SELECT avg(cost), var_pop(cost), var_samp(cost)
FROM movies;
```

The result set shows the following data:

avg(cost)	var_pop(cost)	var_samp(cost)
19.167273	52.806254	53.345094

The interface also includes a Schemata panel on the right showing the database structure, and a Syntax panel at the bottom right with categories like Data Manipulation, Data Definition, MySQL Utility, and Transactional and Locking.

As we saw with the VARIANCE statistic, there are also population and sample statistics for the standard deviation.

The screenshot shows the MySQL Query Browser interface. The title bar indicates the connection is to 'sqlf401@cisdb03.msjc.edu:3306 / movies'. The query editor contains the following SQL statement:

```
SELECT avg(cost), stddev_pop(cost), stddev_samp(cost)
FROM movies;
```

The 'Execute' button is highlighted. Below the query editor, the 'Resultset 1' tab is active, displaying a table with the following data:

avg(cost)	stddev_pop(cost)	stddev_samp(c...
19.167273	7.266791	7.303773

The status bar at the bottom indicates '1 row fetched in 0.0025s (0.0303)'. The right sidebar shows the 'Schemata' tab with a tree view of the database structure, including 'information_schema' and 'movies'. The 'Syntax' tab is also visible, showing a list of SQL topics.

Module 12: Set Functions

Page I-1: WHERE clause

We can use the where clause in tandem with the column functions.

In this example we're looking for the oldest foreign-born client.

In a subsequent module we'll re-examine the SQL processing model and try to better understand how all of the pieces fit together. Until then, you should 'give it a go'.

Which comes first, now?

```
SELECT
FROM
WHERE
ORDER BY
```

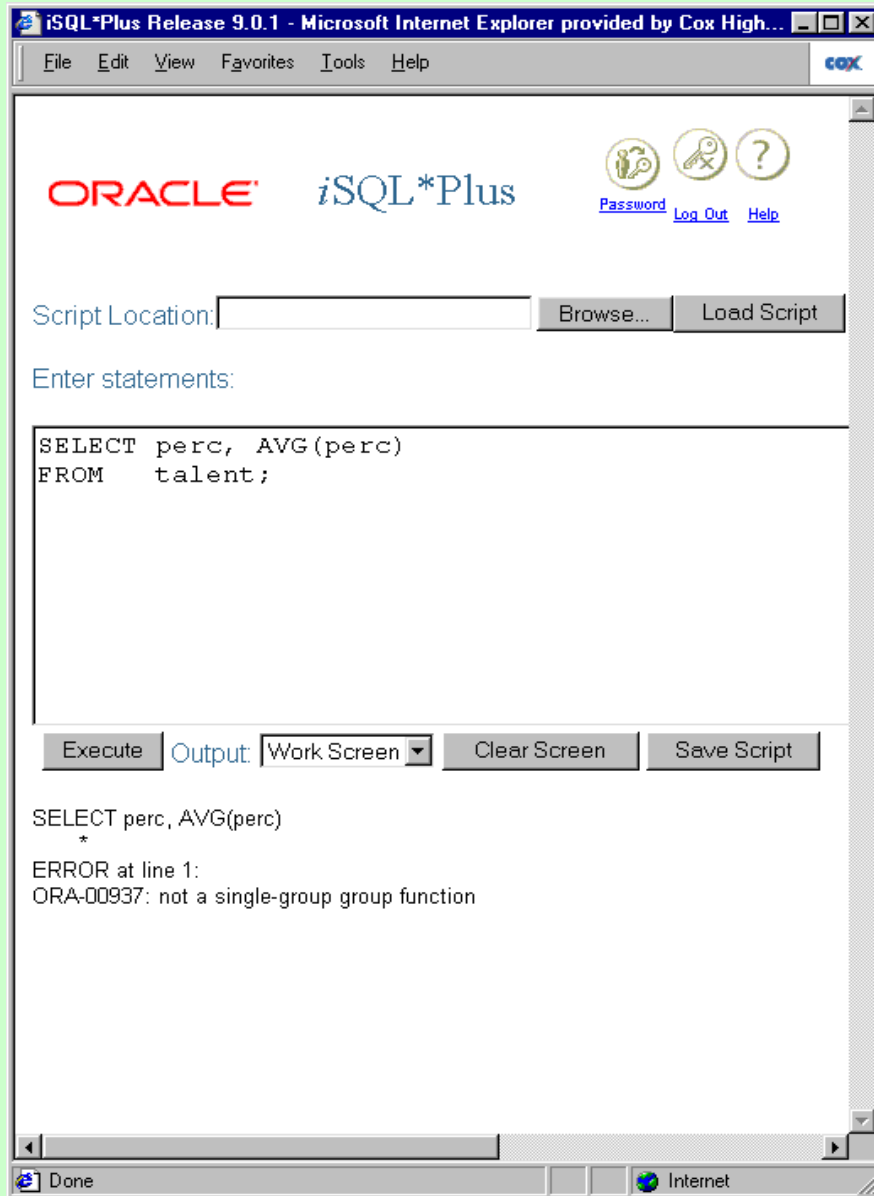

Module 12: Set Functions

Page S-1: Summary

The set functions that we examined in this module can be used to gather and display statistical information about the data base.

This statistical information is, by it's nature, a summary or an aggregation about some aspect of the data.

Summary information cannot be combined with detail information, else SQL will throw an error. As the slide to the left demonstrates.

Group function, set function, aggregate function

COUNT(column-name), COUNT(*)

SUM()

MIN()

MAX()

AVG()

Tally

STDDEV()

VARIANCE()

Collating sequence

Character set

extrema

Please drop me an email if you noticed any errors in this module. I'd also appreciate reading your comments, criticisms, and or suggestions as to how this module could be improved.

Thanks,

bil

That's All
